*A continuous function can not change its <http://planetmath.org/SignumFunction> sign without going through the zero.*

This contents of Bolzano's theorem may be formulated more precisely as the

**Theorem.** If a real function  $f$  is continuous on a closed interval  $I$  and the values of  $f$  in the end points of  $I$  have <http://planetmath.org/Positiveopposite> signs, then there exists a zero of this function inside the interval.

The theorem is used when using the interval halving method for getting an approximate value of a root of an equation of the form  $f(x) = 0$ .
